What problem are we solving?

Developers cannot always resolve their questions from Zebra’s instructions and may spend time seeking help.

Zebra’s documentation team needs evidence showing what information is missing or hard to understand.

We must distinguish a documentation problem from a failure to find or use existing information.

What did we accomplish last week?

We archived one public case and a static report in the main project, and kept two earlier model responses as separate observations.

The developer wants a web app to use Zebra device features, including starting a scan with an on-screen button.

These saved materials do not establish accuracy, and the new integrated version still needs deployment and browser checks.

What does the case actually show?

Zebra’s DataWedge 15.0 guide describes commands that start or stop scanning when the required scanner settings are enabled.

That does not establish how a button in Chrome can send those commands, or whether they work on the developer’s device.

This report checks one of seven requested features, with no new model run or device test, so the finding remains unresolved.

What comes next, and where do we need help?

Next week, we propose to test one question under fixed conditions and show the question, source, answer, and explanation of any failure.

Before expanding the demo, we need to agree with Zebra on what counts as a correct and useful answer.

Can FORGE help us confirm that scope and review standard?
